

# TA6.2: Peat Landslide Hazard and Risk Assessment

## Ben Sca Redesign Wind Farm

### Ben Sca Wind Farm Limited

Prepared by:

**SLR Consulting Limited**

No. 50 Stirling Business Centre, Wellgreen, Stirling,  
FK8 2DZ

SLR Project No.: 405.064982.00001

14 March 2024

Revision: 1

## Basis of Report

This document has been prepared by SLR Consulting Limited (SLR) with reasonable skill, care and diligence, and taking account of the timescales and resources devoted to it by agreement with Ben Sca Wind Farm Limited (the Client) as part or all of the services it has been appointed by the Client to carry out. It is subject to the terms and conditions of that appointment.

SLR shall not be liable for the use of or reliance on any information, advice, recommendations and opinions in this document for any purpose by any person other than the Client. Reliance may be granted to a third party only in the event that SLR and the third party have executed a reliance agreement or collateral warranty.

Information reported herein may be based on the interpretation of public domain data collected by SLR, and/or information supplied by the Client and/or its other advisors and associates. These data have been accepted in good faith as being accurate and valid.

The copyright and intellectual property in all drawings, reports, specifications, bills of quantities, calculations and other information set out in this report remain vested in SLR unless the terms of appointment state otherwise.

This document may contain information of a specialised and/or highly technical nature and the Client is advised to seek clarification on any elements which may be unclear to it.

Information, advice, recommendations and opinions in this document should only be relied upon in the context of the whole document and any documents referenced explicitly herein and should then only be used within the context of the appointment.

## 1.0 Introduction

### 1.1 General

SLR Consulting Ltd (SLR) was commissioned by Ben Sca Wind Farm Limited (The Applicant) to undertake a Peat Landslide Hazard and Risk Assessment (PLHRA) for the proposed Ben Sca Redesign Wind Farm (hereafter referred to as the “Proposed Development”). The location of the Proposed Development is shown on **Figure 6.2.1** within the site boundary (hereafter referred to as “the site”).

The Proposed Development is located approximately 2.5km southwest of Edinbane and 7km to the east of Dunvegan on the Isle of Skye. The Proposed Development would comprise of nine wind turbines with associated infrastructure including access tracks, crane hardstandings, borrow pits, substation and two construction compounds (one permanent, one temporary). Full details of the Proposed Development are provided in **EIA Report Chapter 1: Introduction and Project Description**.

The purpose of this report is to consider the extent of peat and potential peat slide hazard at the Proposed Development and consider the potential impact to the Proposed Development, such that areas of deep peat and areas at high risk of a peat slide can be avoided during the design phase.

This PLHRA has been prepared using data collected at the Proposed Development from 2018 to 2021, supplemented with additional peat survey data collected in 2023 and 2024. If the Proposed Development is approved, this PLHRA would replace the previous PLHRA provided as Technical Appendix 10.1 in the EIA Report for the original Ben Sca Wind Farm (SLR, 2020) which was consented in December 2020.

The work has been undertaken by a team of Geotechnical Engineers and Geologists, with over 10 years’ experience in undertaking peat assessments. The team was led by a Chartered Hydrogeologist with 30 years’ consultancy experience and specialising in the assessment of soils, geology and water for renewable power projects in Scotland.

The methods adopted for the assessment follow the best practice guidance<sup>1</sup> issued by the Scottish Government for investigation, assessment and reporting for wind farms in peat areas. The guidance provides a screening tool to determine whether a PLHRA is required. The requirements to undertake a PLHRA are when blanket peat is present, slopes exceed 2° and the proposed infrastructure is located on peat. These conditions exist at the Proposed Development and therefore a PLHRA is required.

Where relevant, reference is also made to guidance published by the Scottish Environment Protection Agency (SEPA) and wind farm construction good practice guidance.

### 1.2 Scope and Objectives of the Report

The purpose of a report is to identify those parts of the Proposed Development that are naturally susceptible to a higher risk of instability so that they can be avoided or accommodated. It should be noted that all peat slopes have a risk of instability and the vast majority of peat slope failures occur naturally.

The peat stability assessment is primarily concerned with the influence of the peat on the development of the wind farm. The main objective is to assess the potential peat stability at the Proposed Development, identify areas of potential concern and identify mitigation measures to ensure the maintenance of peat stability before, during and after construction.

---

<sup>1</sup> Peat Landslide Hazard and Risk Assessments (Scottish Government, April 2017)

All aspects of construction should be based on ensuring minimum disruption to the peat areas. The objectives have been achieved by completion of the following:

- a desk-based review of available reports which include geological, hydrological and topographical information;
- Phase 1 & 2 peat depth surveys undertaken by SLR;
- geomorphological mapping of the Proposed Development to identify the prevailing conditions influencing the potential for, or any evidence of, active, incipient or relict peat instability, including identification of the location and photographic record, as appropriate;
- reporting on evidence of any active, incipient or relict peat instability, and the potential risk of future instability, describing the likely causes and contributory factors;
- identification of potential controls to be imposed on the Contractors for the Works to minimise the risk of peat instability occurring at the Proposed Development; and
- provide recommendations for further work or specific construction methodologies to suit the ground conditions at the Proposed Development to mitigate any unacceptable risk of potential peat instability.

It is a requirement of all renewable energy developments to follow a very carefully worded and designed Construction and Environmental Management Plan (CEMP) which uses many of the recommendations of the PLHRA.

Without the guidance contained in a Construction Method Statement or CEMP, the following factors would increase the risk of instability:

- construction of access tracks;
- excavation and stockpiling for foundations;
- construction of hardstanding area; and
- blocking of natural drainage, inappropriate new drainage or drainage discharge.

It is important to note that peat instability and the impacts of any instability are not constrained by artificial site or ownership boundaries but by topographic and geomorphologic boundaries. It is therefore important to ensure that the breadth of scope of any assessment adequately covers the areal extent of possible impact.

The risk assessment is based on ground models developed using a Geographical Information System (GIS) specifically for this Proposed Development. A numerical analysis was undertaken in which coefficients were allocated for each of the factors influencing peat stability and their impact on possible receptors.

The conceptual layout of the wind turbines and access routes, the findings from the peat probing, sampling and analysis were used by the design team to optimise the wind turbine layout to avoid or mitigate areas of unacceptable peat slide risk. The layout presented in the drawings represents the final iteration of the wind turbine layout.

This system outlined above was developed in accordance with the guidelines on PLHRA by the Scottish Government<sup>1</sup> for the investigation, assessment, and reporting for wind farms in peat areas. The analysis and interpretation are based upon the results obtained from this process as well as previous experience and the results of case studies elsewhere. Where deviations from this guidance have occurred, this is highlighted and explained in the text.

## 2.0 Peat Instability

The importance of assessing the stability of peat deposits in relation to energy developments came to the fore as a result of peat failures during the construction of Derrybrien<sup>2</sup> Wind Farm in Ireland in 2003. Although no fatalities were associated with these failures, there was a significant environmental impact. Windfarms tend to be constructed in high moorland areas which are associated with significant peat deposits (typically blanket bogs). There is a potential for peat instability to occur, particularly where deposits are in excess of 1m thick. Peat instability is influenced by many factors, including, but not limited to, peat thickness, hill slope gradient, underlying geology and subsurface hydrology.

This section reviews the nature of peat and how current and past activities can influence stability. The factors which are likely to influence the potential for peat instability are:

- significant peat depths over impermeable bedrock or minimal soil;
- the presence of slope gradients greater than 4° (approximately) and general topography;
- natural drainage paths;
- evidence of past failures, including soil creep;
- drainage features at the base of slopes which could lead to undercutting;
- forestry plantations and artificial drainage; and
- recent climate patterns.

It should be noted that peat instability is not a recent phenomenon and there is documentary evidence of peat landslides dating back over 500 years<sup>3</sup>. Many landslides that involve peat have no human interference that could be considered as a trigger and this should be borne in mind when considering the susceptibility of a site to potential instability.

### 2.1 Background Information Regarding Peat

Peat is found in extensive areas in the upland and lowland regions of the UK and is defined as the partly decomposed plant remains that have accumulated in-situ, rather than being deposited by sedimentation. When peat forming plants die, they do not decay completely as their remains become waterlogged due to regular rainfall. The effect of water logging is to exclude air and hence limit the degree of decomposition. Consequently, instead of decaying to carbon dioxide and water, the partially decomposed material is incorporated into the underlying material and the peat 'grows' in-situ.

Peat is characterised by low density, high moisture content, high compressibility and low shear strength, all of which are related to the degree of decomposition and hence residual plant fabric and structure. To some extent, it is this structure that affects the retention or expulsion of water in the system and differentiates one peat from another.

Lindsay<sup>4</sup> defined two main types of peat bog, raised bog and blanket bog, which are prevalent on the west coast of Europe along the Atlantic seaboard. In Britain, the dominant peatland is blanket bog which occurs on the gentle slopes of upland plateaux, ridges and benches and is predominantly supplied with water and nutrients in the form of precipitation. Blanket peat is usually considered to be hydrologically disconnected from the underlying mineral layer.

---

4 Lindsay, R.A., (1995), 'Bogs: The ecology, classification and conservation of Ombrotrophic Mires.' Scottish Natural Heritage, Perth.

There are two distinct layers within a peat bog, the upper acrotelm and the lower catotelm. The acrotelm is the fibrous surface to the peat bog<sup>5</sup>, typically less than 0.5m thick; which exists between the growing bog surface and the lowest position of the water table in dry summers. Below this are various stages of decomposition of the vegetation as it slowly becomes assimilated into the body of the peat.

For geotechnical purposes the degree of decomposition (humification) can be estimated in the field by applying the 'squeezing test' proposed by von Post and Grunland<sup>6</sup>. The humification value ranges from H1 (no decomposition) to H10 (highly decomposed). The extended system set out by Hobbs<sup>7</sup> provides a means of correlating the types of peat with their physical, chemical and structural properties.

The relative position of the water table within the peat controls the balance between accumulation and decomposition and therefore its stability, hence artificial adjustment of the water table by drainage requires careful consideration.

## 2.2 Peat Shear Strength

In geotechnical terms, the shear strength of a soil is the physical characteristic that provides stability and coherence to a body of soil. For mineral soils such as clays or sands, such strength is variously given by an inter-particle friction value and cohesion. Depending on whether the mineral soil is predominantly cohesive (clay) or non-cohesive (sand) governs which of the components of strength control the behaviour of the soil.

For peat soils, where the major constituent is organic and there is likely to be little or no mineral component, the geotechnical definition of shear strength does not strictly apply. At present there is no real alternative method for defining the shear strength of peat, therefore the geotechnical definition is generally adopted, in the knowledge that it should be used with great caution.

As noted previously, the acrotelm or near surface peat comprises a tangle of fresh and slightly rotted roots and vegetable fibres. These roots and fibres impart a significant tensile shear strength capacity to the material which provides it with a significant load carrying capacity. The acrotelm is, in effect, a fibre reinforced soil.

In the more decomposed catotelm, the tensile shear strength is reduced as the roots and fibres become more rotted. However, the loss in strength due to decomposition is off-set to a limited degree, by a gain in strength due to the overburden pressure. In geotechnical engineering there is an established relationship for recently deposited soils, between the shear strength of a sample and the thickness of overburden above it.

Consequently, it is almost impossible to predict a shear strength profile in peat and attempts to measure the shear strength using normal geotechnical methods can be misleading. Typical values of shear strength from hand shear vanes would be in the range 10-60 kilopascal (kPa) although values over 100kPa have been recorded in peat elsewhere. The higher strengths are almost certainly the influence of roots or other non-decomposed material. It is believed that the strength of peat should be quoted as a cohesion value as there are few, if any, discrete particles to give the material a significant frictional resistance. It should be noted, however, that any quotation of shear strength for peat should be treated with extreme caution.

## 2.2.1 Peat Stability – Factors to be Considered

There is considerable observational information relating to debris and peat flows although the actual mechanisms involved in peat instability are not fully understood. The main influences on slope stability are geological, geotechnical, geomorphic, hydrological, topographic, climatic, agricultural and human influences such as drainage and construction activity. Peat is affected to a degree by changes in any of the above list and it is vital to appreciate that changes to the existing equilibrium would affect the level of slope stability during construction and operation of the Development.

Some of the contributory factors to peat instability are summarised below:

- The geographical limits which could be affected by potential instability are not confined to the artificial boundaries imposed by land ownership; landslip occurring above a site could affect the Proposed Development and property down slope or downstream of the Proposed Development for several kilometres.
- Agriculture and grazing have a substantial effect on peat areas and this can be compounded in areas that have been managed to improve grazing. Grazing compacts the peat surface reducing the rainwater infiltration and the additional nutrients change the ecological balance of the original peat bog. Agricultural management can include surface drainage and periodic burning, both of which can leave the surface of the peat bare for a period of time resulting in temporary desiccation of the surface. Subsequent wetting of the peat and resumption of peat accumulation results in the former desiccated and possibly ash covered surface being incorporated into the body of the peat which introduces a weak discontinuity in the profile; this in turn becomes another unknown factor in the stability assessment.
- Forestry has a substantial effect on slope stability particularly in the early stages as the creation of a forest involves disruption of the natural equilibrium and drainage of the slopes and the installation of artificial drains by deep ploughing. The construction of access tracks further disrupts the drainage and concentrates groundwater flow into narrow, fast flowing erosive streams. The work by Winter et al <sup>8</sup> noted that forest tracks can act to retard or concentrate the down slope flow of water and thus aid its penetration into the slope below. Such a mechanism has been observed at a number of recent landslips that have affected the road network in Scotland.
- Natural Drainage – some of the precipitation falling onto a natural upland peat bog would be absorbed into the low permeability catotelm peat. However, most of the water would run-off as sheet flow through upper, high permeability acrotelm. Thus, the water is transmitted to the lower slopes in a reasonably controlled manner through a range of interconnections that operate at different scales and speed. Failure to understand this and to disrupt the transmission process for the groundwater could result in instability.
- Artificial Drainage - Where artificial drainage has been used to improve the quality of the grazing or to promote forestry it reduces the overall volume of water entering the bog and transfers this water to the edges more rapidly. This can result in ditches and streams becoming enlarged, causing increased erosion and a greater silt burden in the stream water.

## 2.3 Peat Mass Stability

The principal surface indicator of peat slide potential is cracking of the peat land surface and it is the identification of crack patterns in the field and the attendant causes of the cracking that is fundamental to a peat stability assessment.

Sites that have exhibited natural instability in the past are likely to be more susceptible to future instability during and following construction of a renewable energy development, therefore it is important to identify such instability as part of the Peat Stability Assessment.

### 2.3.1 Types of Failure

The result of instability in peat is the down-slope mass movement of the material; there are a number of definitions of peat instability which are used to characterise the type of failure. A brief description is given as follows:

- bog bursts or bog flows – the emergence of a fluid form of well humified, amorphous peat from the surface of a bog, followed by the settling of the residual peat, in-situ<sup>9</sup>;
- peat slides – the failure of the peat at or below the peat/ substratum interface leading to translational sliding of detached blocks of surface vegetation together with the whole underlying peat stratum<sup>9</sup>; and
- bog slide – an intermediate form of instability where failure occurs on a surface within the peat mass with rafts of surface vegetation being carried by the movement of a mass of liquid peat.

### 2.3.2 Bog Bursts

Accounts of bog bursts are generally associated with very wet climates or areas which have received storm rainfall events. Bog bursts can be associated with particularly wet peat landscapes; therefore, it is possible to identify broad regions of a higher susceptibility to these failures. The constraints used to identify the areas of higher susceptibility to bog burst failure are given below:

- peat thickness in excess of 1.5m with no upper limit;
- shallow gradients, generally within the range of 2 to 10°, peat thicker than 1.5m is generally not observed on slopes steeper than 10°, also moisture content is generally reduced on steeper slopes due to drainage);
- ground which is annually waterlogged to within the upper 1m below ground level, (the groundwater level may rise above this but rarely falls below)<sup>10</sup>;
- greater humification of the lower catotelm within the waterlogged ground; and
- lower surface tensile strength of the fibrous peat and vegetation.

The humified mass can be considered as analogous to a heavy liquid and the stability of this mass is maintained by the strength of the surface or acrotelm peat. Should the surface become weakened through erosion or desiccation or the construction of a surface drainage ditch for agricultural or forestry reasons or through turbary (peat cutting), failure is made more likely.

### 2.3.3 Peat Slides

Peat slides tend to be translational failures with a defined shear surface at or close to the interface with the substrate.

---

9 Dykes, A.P and Kirk, K.J., (2001), 'Initiation of a multiple peat slide on Cuilcagh Mountain, Northern Ireland.' *Earth Surface Processes and Landforms*, 26, 395-408.

10 Crisp, D.T., Dawes, M. & Welch, D. (1964), 'A Pennine Peat Slide', *The Geographical Journal*, Vol 130, No4, pp519-524.

The factors generally considered to influence susceptibility to peat slide failures are listed below:

- peat depth up to 2m;
- slope gradients between 5° and 15°;
- natural or artificial drainage cut into the surrounding peat landscape;
- greater humification of the lower catotelm within the waterlogged ground; and
- lower surface tensile strength of the fibrous peat and vegetation.

It is noted that some of the factors causing instability are common to both bog bursts and peat slides.

The peat – substrate interface is the primary zone of failure and is enhanced by elevated water content at this boundary and softening or weathering of the lower mineral surface. For this reason, any investigation or probing should try to distinguish the nature of the lower mineral substrate.

#### **2.3.4 Bog Slides**

A bog slide is a variation on a peat slide where part of the peat mass is subject to movement, usually on an internal layer of material, which may be more prone to movement, such as an interface between the acrotelmic and catotelmic layer.

#### **2.3.5 Natural Instability**

The stability of a peat mass is maintained by a complex interrelationship of many factors, some of which may not be immediately obvious. Key factors include sloping rock head and proximity to a water body. Rainfall often acts as the trigger after the slope has already been conditioned to fail by natural processes.

It should also be remembered that peat bogs are growing environments and that there would come a time, on sloping ground, where the forces causing instability, the weight of the bog, can no longer be resisted by the internal strength of the peat and its interface with the underlying mineral surface. At this point, failure would occur.

The weight of the peat bog or any soils mantling steep hill slopes would be increased during periods of very heavy rain and it is common to see landslips occurring following extreme rain events. This may be a concern for future developments where one of the predicted effects of global warming will be a greater frequency of extreme weather, intense storms being one element.

## 3.0 Desk Based Review

### 3.1 Site Description

The site is located approximately 2km south of Edinbane and 7km to the east of Dunvegan on the Isle of Skye at National Grid Reference (NGR) 132800, 848600.

The site is currently accessed via the existing Ben Aketil Wind Farm access track off the A850 (Photograph 3). It is proposed that spurs will be created from the existing Ben Aketil access track to construct the Proposed Development.

The site is characterised by smoothed stepped moorland, with a coniferous woodland plantation along its northern edge. The northwest of the site incorporates a section of the coniferous woodland plantation. A number of small tributaries run through the site and eventually join larger watercourses to the north, such as Red Burn and Kerral Burn.

The site is predominately used for game shooting. The surrounding area is rural in nature, with land predominately used for agriculture, grazing, forestry and game shooting.

The site is surrounded by two operational wind farms. To the east, the operational Edinbane Wind Farm is located comprising 18 turbines which extend in a north to south direction between Airgh Neil and Glen Vic Askill (Photograph 2). To the west, lies the operational Ben Aketil Wind Farm (and extension) which forms a linear development comprising 12 turbines (Photograph 3). Ben Aketil Wind Farm (and extension) extends in a northwest to southeast orientation to the northwest of the summit of Ben Aketil (266 m AOD).

**Photo 1: View southwest towards Ben Aketil Wind Farm from NGR 32522 49808**

**Photo 2: View towards Edinbane Wind Farm looking east from NGR 34633 48144**

**Photo 3: View southwards on Ben Aketil access track from NGR 31990 49224**

### 3.2 Topography

Based on the digital terrain model available from the British Geological Society (BGS) Geoindex<sup>11</sup>, the Proposed Development area characterised by upland plateau, rounded

---

<sup>11</sup> British Geological Society (BGS), Geoindex Onshore, Available online at: [https://mapapps2.bgs.ac.uk/geoindex/home.html?\\_ga](https://mapapps2.bgs.ac.uk/geoindex/home.html?_ga)

ridges, craggy outcrops and irregular slopes. Topography ranges from approximately 170m to 283m AOD with the southern extent of the proposed site forming the most elevated section at Ben Sca (283m AOD). To the north of the summit of Ben Sca, a ridgeline extends in a northwest direction (Mullach Ben Sca) and includes a series of smaller summits descending to 200 m AOD.

### 3.3 Geology

#### 3.3.1 Superficial Geology

BGS mapping indicates that peat is mapped extensively across the site, with bedrock found at or close to the surface on the summits of many of the hills.

**Figure 6.2.3** contained within this report details the superficial geology BGS mapping overlaid across the Proposed Development.

#### 3.3.2 Bedrock Geology

BGS mapping indicates the solid geology of the Proposed Development comprises Palaeogene age extrusive igneous rocks of mafic (predominately basaltic composition) lava/tuff.

**Figure 6.2.4** contained within this report details the bedrock geology BGS mapping overlaid across the Proposed Development.

### 3.4 Peatland Classification

The Scottish Government, Carbon and Peatland Map 2016<sup>12</sup> indicates that Class 1 peat covers the full Proposed Development area. Class 1 peat consists of carbon-rich soils, potentially deep peat and priority peatland habitats that are likely to be of high conservation value.

### 3.5 Mining & Quarrying

Following review of publicly available records, there is no evidence of mining or quarrying within the site boundary or immediate surrounds, except for small forestry borrow pits used for track construction and a borrow pit previously used for Ben Aketil Wind Farm which has been restored.

### 3.6 Hydrology and Hydrogeology

#### 3.6.1 Hydrology

The site lies within two river catchments, the Red Burn and the Abhainn Choishleader. The Scottish Environment Protection Agency (SEPA) Water Classification Hub has assigned an overall quality rating of “Good” to both watercourses.

A number of watercourses are present on the site; Allt a’ Choire and Allt Donachaidh to the south and west, Allt Cro nan Caorach, Allt Storachan and Abhainn Choishleadar to the north and east.

#### 3.6.2 Hydrogeology

The BGS groundwater vulnerability and regional hydrogeological mapping confirm that the superficial deposits, where present, and the bedrock beneath the site are unlikely to contain

---

<sup>12</sup> Scottish Government, Carbon and Peatland Map 2016, Available online at: [map.environment.gov.scot/soil\\_maps/](http://map.environment.gov.scot/soil_maps/)

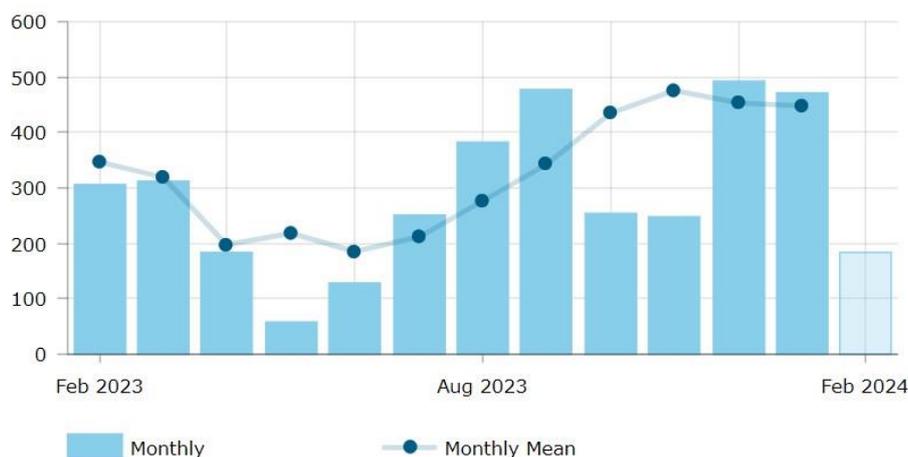

significant quantities of groundwater. The BGS classify the bedrock as a low productivity aquifer, whereby small amounts of groundwater may be present within the near surface weathered zone or secondary fractures.

### 3.7 Rainfall

Periods of intense heavy rainfall are often seen as triggers for instability events. Rainfall data from the closest SEPA weather station, Allt Dearg House, shows the average monthly rainfall in the region from February 2023 until February 2024. The highest monthly rainfall was 492mm in December 2023. The lowest monthly rainfall was 58.2mm in May 2023.

#### Monthly Rainfall at Allt Dearg House Station

### 3.8 Geomorphology

The site is generally characterised as an undulating moorland with lower lying areas to the north and craggy outcrops to the east and the south. The steepest slopes are present to the southwest and to the east of the site. A detailed geomorphology map is detailed on **Figure 6.2.5** with the main geomorphological features detailed below.

#### 3.8.1 Aerial Photography Interpretation and Site Observations

The aerial photographs were used for the Proposed Development to identify the major geomorphological features such as the breaks of slope and landslips. These were inspected where identified during site visits when more detailed assessment was undertaken. Typical site conditions observed throughout the site are shown below in Photos 1, 2, and 3.

**Photo 1: View facing southeast across hagsgs on track between proposed turbines 2 and 3, taken from NGR 133248, 848137**

**Photo 2: View facing east across exposed bedrock near proposed turbine 6, taken from NGR 132778, 848898**

**Photo 3: View facing north of artificial drainage trending north-south at the location of proposed turbine 7, taken from NGR 132530, 849195**

Aerial photography using google earth was reviewed dating back to 1985 with images from 2005, 2009, 2013, 2018 to 2023 reviewed. Interpretation of available aerial photographs was undertaken to assess and identify evidence of historic peat instability. The photographs were examined to identify features of interest, such as:

- possible extension and/or compression features.
- areas of historic failure scars and debris.
- evidence of peat creep.
- areas with apparently poor drainage.
- areas with concentrations of surface drainage networks.
- steeply incised stream cuttings within peat deposits.
- areas with peat drift recorded on steep slopes.

The main features are detailed below.

### **3.8.2 Peat**

Peat is locally extensive across the site. Deposits are localised and associated with topographic lows, hollows, gentle slopes and flatter expanses that allow for the formation of peat.

Localised deep peat deposits are located at:

- the proposed substation compound in the south of the site with peat depths of 1-1.5m recorded;
- the location of proposed turbine 4 with peat depths between 1-2m mapped east of the proposed hardstanding;
- the proposed length of track between proposed turbines 3 and 4 with peat depths of 1-1.5m with shallower peat depths mapped to the northeast;
- the location of proposed turbine 5 with peat depths between 1-1.5m in the northern section of the hardstanding;
- the proposed track between proposed turbines 5 and 6 with an area of deep peat with shallower depths to the southwest;
- an extensive area northwest of the hardstanding at proposed turbine 6 which extends towards proposed turbine 7 where depths of 1-1.5m are mapped; and
- an area in close proximity to the proposed construction compound in the north of the site (previously used for Ben Aketil Wind Farm).

Observations from site visits and the habitat surveys indicate that some of the areas of peat across the site are blanket bog. Areas of blanket bog are present west of proposed turbine 4 extending to Ben Aketil Wind Farm. Further areas of blanket bog were surveyed east of Ben Sca summit extending to Edinbane Wind Farm.

Based on peat sampling during site visits, the peat across the site is typically fibrous and pseudo-fibrous.

### **3.8.3 Peat Haggs**

Peat haggs were extensive across the site as detailed on the geomorphology mapping.

### **3.8.4 Drainage**

Drainage across the site is characterised by a network of streams and rivers associated with the Allt a' Choire, Abhainn Choishleadar, Aketil Burn, Red Burn and Rageary Burn.

There are extensive areas of anthropogenic drainage relating to the commercial forestry within the site. Most of these furrows are north to south trending.

### **3.8.5 Forestry**

Forestry is only located in the north of the site. This area of forestry is coniferous in nature and of poor growth and quality. A small area of deciduous woodland is located near Rageary Burn which is situated 2km west of the site and a larger area 0.5km northwest of Beinn a' Chlerich.

### **3.8.6 Bedrock**

The OS mapping and aerial photography indicate frequent exposures of bedrock across the site. This was confirmed during the survey where bedrock outcrops were frequently observed and recorded north of Ben Sca summit and to the southeast of Ben Aketil Wind Farm. There were also areas of exposed bedrock recorded during the site survey east of Ben Aketil Wind Farm and northeast of Mullach Ben Sca.

### **3.8.7 Extension/Compression Features**

There was no visible evidence in the aerial photographs or site walkovers of any extension or compression features in the peat. In addition, it was not possible to identify evidence of any significant historic peat failures or slides on the site from the aerial photographs.

## 4.0 Site Work

### 4.1 Peat Surveys

The surveys carried out followed best practice guidance for developments on peatland<sup>13,14,15</sup>. The surveys were undertaken across a number of phases on the dates listed below:

- Phase 1 May 2018;
- Phase 2 April 2019;
- additional Phase 2 August 2021 (targeting layout of Ben Sca Wind Farm Extension);
- additional Phase 2 September 2023 (targeting layout of Ben Sca Redesign Wind Farm); and
- additional Phase 2 February 2024 (targeting updates to the layout of Ben Sca Redesign Wind Farm)

Phase 1 peat probing resulted in probing on a 100m grid to allow for initial assessment of the Proposed Development and Phase 2 probing saw detailed probing undertaken across the proposed layout, focussing on access tracks, turbine locations and other site infrastructure. Probing was undertaken at 25- 50m intervals across linear features and at a density of 10m x 10m across the remaining infrastructure.

Peat is generally defined as an organic soil in excess of 0.5m, if the soil is less than 0.5m, then it is considered peaty soil. The peat was found to vary across the site in terms of thickness and coverage.

Thin peat was classed as being 0.5m to 1.5m thick, with deposits in excess of this being classed as thick peat. The thickness ranges used were intended to reflect the probability of instability associated with both peat slides (in thin peat) and bog slides. Where the probing recorded less than 0.5m thick, this has been considered to be an organic/peaty soil rather than peat.

The thickness of the peat was assessed using a graduated peat probe, approximately 6mm diameter and capable of probing depths of up to 10m. This was pushed vertically into the peat to refusal and the depth recorded, together with a unique location number and the co-ordinates from a handheld Global Positioning System instrument (GPS). The accuracy of the GPS was quoted as  $\pm 2\text{m}$ , which was considered sufficiently accurate for this survey. All data was uploaded into a GIS database for incorporation into various drawings and analysis assessments.

Where the peat probing met refusal on a hard substrate, the 'feel' of the refusal can provide an insight into the nature of the substrate. The following criteria were used to assess material:

- solid and abrupt refusal – rock;
- solid but less abrupt refusal with grinding or crunching sound – sand or gravel or weathered rock;
- rapid and firm refusal – clay; or
- gradual refusal – dense peat or soft clay.

---

13 Scottish Renewables & SEPA (2012) 'Developments on Peatland Guidance on the Assessment of Peat Volumes, Reuse of Excavated Peat and the Minimisation of Waste'.

14 Scottish Natural Heritage (SNH), SEPA, Scottish Government & James Hutton Institute. (2014) 'Peat Survey Guidance; Developments on Peatland: Site Surveys'.

15 Scottish Government, Scottish Natural Heritage, SEPA (2017) Peatland Survey. Guidance on Developments on Peatland, on-line version only

An assessment of the substrate was made and recorded at each probe hole. For use within this assessment, engineering judgement has been used to assess the substrate at probes undertaken by other parties.

The relative stiffness of the peat was also assessed from the resistance to penetration of the probe and to the effort required to extract the probes (retrieval of the probe was often impossible for one person). In all instances refusal was met on obstructions allowing identification of subsurface geology.

## 4.2 Peat Depth

The results from all probing exercises listed above in Section 4.1 are detailed in the following sections and the peat depths identified on-site are shown on **Figure 6.2.6** and **Figure 6.2.7**. All probing data is provided in **Annex 6.2A**.

The peat was found to vary across the site in terms of thickness and coverage. The slopes on-site are detailed on **Figure 6.2.8**. When viewed in conjunction with peat depth figures, it is evident that the peat is generally limited to flatter lying topographic areas. There were localised areas of peat, defined by topography and undulating bedrock. Deeper peat was generally encountered in flatter, lower gradient areas of the site.

A total of 3,032 peat probes were undertaken across all survey phases, with the results summarised in **Table 6.2A**.

**Table 6.2A: Peat Probing Results**

Peat Thickness (m)	No. of Probes	Percentage (of total probes undertaken on-site)
0 (no peat)	126	4.2
0 – 0.49 (peaty soil)	1373	45.3
0.50 – 0.99 (thin peat)	874	28.8
1.00 – 1.49 (thin peat)	318	10.5
1.50 – 1.99 (thick peat)	211	7.0
2.00 – 2.49 (thick peat)	67	2.2
2.50 – 2.99 (thick peat)	39	1.3
3.00 – 3.49 (thick peat)	17	0.6
3.50 – 3.99 (thick peat)	7	0.2
> 4.0 (thick peat)	0	0.0

The peat was found to vary across the site in terms of thickness and coverage. It is evident from review of the relevant figures and data that the peat deposits are generally limited to flatter lying topographic areas. There were localised areas of deeper peat (blanket bog), defined by topography.

## 4.3 Peat Condition

Peat exposures were visually assessed and core locations were taken adjacent to the Proposed Development (for the proposed Balmeanach Wind Farm EIA). Peat samples were collected by SLR in June and August 2023 using a peat auger and used to inform interpretations of the peat condition and underlying substrate. Peat is described using the von Post<sup>6</sup> classification.

Based on interpretations from probing and peat core samples, the peat is predominantly fibrous and pseudo-fibrous, with H values of H3-H4 in the acrotelm and values of H3-H7 in the underlying catotelm. No amorphous layers were encountered during the peat coring. Peat Core logs and photographs are presented within **Annex 6.2B**.

Where peat was visually identified onsite, it was generally exposed by streams and within hagged areas. These deposits were generally fibrous. Based on field descriptions, most of the shallow peat would be classified as between H2 and H3 in the von Post classification, showing slight decomposition. The deeper peat, in excess of 1.5m is typically more decomposed and generally H5. Peat Core logs and photographs are presented within **Annex 6.2B**.

#### 4.4 Substrate

Where possible, in the SLR investigation, an assessment of the substrate was made, as described previously. From the evidence of the probing and sampling where available, the substrate falls into one of two principal categories:

- granular (sand and/or gravel/weathered rock), of glacial origin and occasionally interbedded with silty sands; and
- rock, no rock samples were recovered from the probe locations although where exposed, the rock is seen to be metamorphic rock.

Limited cohesive horizons were interpreted by the probing and encountered at the base of peat coring. However, it is likely that any cohesive material is weathered silty material at the top of the weathered glacial material.

## 5.0 Hazard and Risk Assessment

### 5.1 Introduction

The Scottish Government Guidance<sup>1</sup> provides an overview of the principles of hazard and risk with respect to peat landslides. The guidance is noted as illustrative only and the developers can present their own methodology providing it is clearly explained and incorporates consideration of the likelihood of instability and the consequences should it occur. The following sections detail the preferred methodology used within this assessment.

A 'Hazard Ranking' system has been applied based on the analysis of risk of peat slide as outlined in the Scottish Government Guidance<sup>1</sup>. This is applied on the principle:

$$\text{Hazard Ranking} = \text{Hazard} \times \text{Exposure}$$

This philosophy can be applied to the assessment carried out so far in the following approach:

$$\text{Hazard Ranking} = \text{Risk Rating} \times \text{Impact Rating}$$

### 5.2 Methodology

The determination of Risk Rating and Impact Rating values is based on a number of variables which impact the likelihood of a peat slide and the relative importance of these variables specific to the Proposed Development.

Similarly, the consequences or Exposure to receptors is dependent on variables including the particular scale of a peat slide, the distance it will travel, and the sensitivity of the receptor.

In the absence of a predefined system, the approach to determining and categorising Risk Rating and Impact Rating is determined on a site-by-site basis. The particular system adopted for the PLHRA is outlined in the following sections.

### 5.3 Slope Stability

The stability of peat is a complex subject and there are numerous inter-relationships that affect the stability.

A quantitative assessment requires a numerical input and such an analysis cannot account for the unquantifiable input required for a comprehensive peat stability assessment. For this reason, a purely quantitative assessment should only be considered as a guide and a qualitative assessment of stability should be used to inform the final recommendations.

The characteristics of the peat failure phenomena have been incorporated in a stability risk assessment to evaluate the risk of instability occurring within the peat areas. The main factors controlling the stability of the peat mass are the surface gradients, the depth and condition of the peat at each location and the type of substrate.

The natural moisture content and undrained shear strength of the peat are important; however, it is generally accepted that where present, the peat would be saturated and have a very low strength. It is believed to be unrealistic to rely on specific values of shear strength to maintain stability when back analysis of failed slopes indicates that there is often a significant discrepancy between measured strength in peat and stability. Shear strength has been assumed to be constant and worst case, throughout this assessment. It has also been assumed, as a worst case, that the groundwater level is coincident with the ground surface.

## 5.4 Risk Rating

The potential for a peat slide to occur during the construction of the Proposed Development depends on several factors, the importance of which can vary from site to site. The factors requiring considerations would typically include:

- peat depth;
- slope gradient;
- substrate material; and
- evidence of instability or potential instability;

Of these, peat depth and slope gradient are considered to be principal factors. Without a sufficient peat depth and a prevailing slope, peat slide hazard would be negligible.

The rating system outlined below differs slightly from that proposed in the Scottish Government Guidance<sup>1</sup> as the system adopted here incorporates three inputs compared to two in the guidance, with the potential impact of substrate added in this section.

The probability of a peat landslide 'Risk Rating' (score) was derived by multiplying the coefficients for the four key factors (with historic instability as 1) together to produce a risk rating which is a measure of the likelihood of peat instability, and this enables potential areas of concern to be highlighted. For the assessment, the following rating system was applied as shown in **Table 6.2B**.

**Table 6.2B: Probability of Peat Landslide**

Risk Rating Coefficient	Potential Stability Risk (Pre-Mitigation)	Action
<5	Negligible	No mitigation action required.
5 - 15	Low	As for Negligible condition plus development of a site-specific construction and management plan for peat areas.
16 - 30	Medium	As for Low condition plus may require mitigation to improve site conditions.
31-50	High	Unacceptable level of risk and the area should be avoided. If unavoidable, detailed investigation and quantitative assessment required to determine stability and sensitivity to minor changes in strength and groundwater regime combined with long term monitoring.
>51	Very High	Unacceptable level of risk, the area should be avoided.

### 5.4.1 Peat Depth

**Table 6.2C** shows the peat depth ranges and their related peat depth coefficients. The ground conditions were assessed by using peat depths recorded during peat probing. Thin peat was classed as being 0.5m to 1.5m thick, with deposits in excess of this being classed as thick. The thickness ranges used are intended to reflect the risk of instability associated with both peat slides (in thin peat) and bog slides. Where the probing recorded peat less than 0.5m thick, this has been considered to be an organic soil rather than peat and are outside the scope of this assessment.

In addition to peat thickness, the presence of existing landslip debris or indicators of meta-stable conditions such as tension cracks or slumping in the peat suggest the material is likely

to become even less stable should the existing ground conditions change. Where evidence of historical slips, collapses, creep or flows is seen, a separate coefficient has been applied.

**Table 6.2C: Coefficients for Peat Depth**

Peat Depth Range	Description	Peat Depth Coefficients
(<0.5 m)	Peaty/organic soil	0
(0.5 – 1.5 m)	Thin Peat	2
(>1.5 m)	Thick Peat	3*
-	Slips /collapses / creep / flows	8

\*Note that thicker peat generally occurs in areas of shallow gradients and records indicate that thick peat does not generally occur on steeper gradients.

### 5.4.2 Slope Gradients

**Table 6.2D** gives the coefficients applied to the categorised slope angles. The slope gradients were assessed by reference to the mapping and particularly the DTM which was used to generate a slope map (**Figure 6.2.8**), from which the gradient at each probe location could be determined and input into the risk rating spread sheet (**Annex 6.2A**). The gradient quoted at each location was based on the average gradient over a 5m grid.

Coefficients for slope gradient have been assigned to ensure the potential for both peat slides (gradients of 4-15°) and bog slides (gradients of 2-10°) are addressed. By simple inspection it is clear that steeper slopes pose a greater risk of instability than shallow gradients. Therefore, a graduated gradient scale from 0° to >12° (the practical maximum gradient on which peat is commonly observed) has been applied.

**Table 6.2D: Coefficients for Slope Gradients**

Slope Angle (°)	Slope Angle Coefficients
Slope <2°	1
2° ≤ Slope <4°	2
4° ≤ Slope <8°	4
8° ≤ Slope <12°	6
>12° Slope	8

### 5.4.3 Substrate

**Table 6.2E** shows the substrate type and their related substrate coefficient. As noted above, most failures in thin peat layers occur at the interface with the underlying substrate; the nature of the substrate has an influence on the probable level of stability.

Peat failures often occur within glacial till deposits in which an iron pan is observed in the upper few centimetres (Dykes and Warburton, 2007)<sup>16</sup>. They have also been observed over glacial till without and obvious iron pan, or over impermeable bedrock. They are rarely cited over permeable bedrock as the formation of peat deposits is deemed to be less likely.

Where sand and/or gravel (derived from glacial till) form the substrate, the effective strength of the interface can be considered to be good with comparatively high friction values. Under these conditions, failure is likely to occur in a zone within the peat, just above the interface.

<sup>16</sup> Dykes A and Warburton J (2007) Mass movements in peat: A formal classification scheme. *Geomorphology* 86, pp. 73–93

Further factors are necessary to cause a failure of this nature (increased pore pressures within the peat) and occurrence of such events is rare.

Where clay forms the interface, there is likely to be a significant zone of softening in the clay (due to saturation at low normal stresses, poor or non-existent vertical drainage and the effect of organic acids), resulting in either very low undrained shear strength or low effective shear strength parameters. The result is that potential shearing could occur either in the peat, on the interface or in the clay; all three possibilities have been documented in the past.

A rock substrate provides a high strength stratum, however, the rock surface can be smooth, and, depending on the dip orientation of the strata, it can provide a very weak interface. For these reasons, at this stage, a rock interface has been given the same risk rating as clay.

**Table 6.2E: Coefficients for Substrate**

Substrate Conditions	Substrate Coefficients
Granular	1
Rock	2
Cohesive	2
Not proven	3
Slip material (Existing materials)	5

Probing across the site indicated primarily granular and bedrock substrates using the refusal method. This was confirmed by coring at selected locations across the proposed infrastructure.

#### 5.4.4 Results

The table of results, included in **Annex 6.2A**, shows that 3,032 probe locations were identified within the extent of the Digital Terrain Model, peat (>0.5 m) was present at 1,533 locations. The stability risk rating identified the following:

- no peat was recorded at 126 locations (4%), hence no risk;
- negligible risk at 1,794 (59%) probe locations;
- low risk at 816 (27%) locations;
- medium risk at 274 (9%) locations; and
- high risk at 22 (1%) locations.

**Figure 6.2.9** presents the interpreted risk of peat instability based on the multiplication of the risk coefficients discussed in **Table 6.2C** to **Table 6.2E**.

### 5.5 Impact Rating

An assessment of the receptors ‘Impact Rating’ of the medium and high risk locations has been undertaken. It should be noted that the impact assessment is primarily concerned with impacts that affect the environment, ecology, public or infrastructure associated with the development, both on-site and potentially off-site. This assessment does not consider the detailed ecological impact of construction induced peat instability; however, the majority of the sensitive on-site receptors are the watercourses and thus the inferred ecological and environmental issues are addressed. The proposed mitigation measures in Section 6.0 would limit the potential for any slope failures into water courses and drainage features hence limit such impacts. The effect a slope failure may have on the construction site and infrastructure can be easily identified. However, the effect of an instability event on features impacted by an

event not associated with the Proposed Development is harder to predict. In order to address this effect, it is not considered appropriate to assess the effect at every potential receptor location close to the Proposed Development; but rather to assess the effect a particular infrastructure feature (track, wind turbine, substation, etc.) would have on the structures or features surrounding it. By adopting such an approach, the assessment of infrastructure features where a risk ranking of 'negligible' or 'low' (assessed in the stability risk assessments described above) is discounted from further assessment.

The impact rating coefficient (score) is derived by multiplying the receptor ranking coefficient (score) by the distance coefficient (score) and the elevation coefficient (score) for each impact receptor associated with a particular infrastructure feature. The ranking process by attributing the different weighting systems to each factor is detailed in the following sub-sections.

### 5.5.1 Receptor Ranking

Receptors are generally nearby structures or features that may be affected by peat movements caused during or following construction. Generally, only receptors immediately down gradient of the infrastructure feature could be affected by peat instability therefore the first phase of feature ranking requires topographic ridges and valleys to be identified across the Proposed Development and surrounding area. From this, receptors at risk from particular infrastructure features can be identified. However, should instability occur on a steep slope, there is the risk of the back scarp of the instability migrating up-slope, there-by affecting areas previously considered not to be at risk.

The main receptors located within the site and surrounding area which could potentially be affected in the event of a peat slide; are primarily watercourses and associated tributaries, existing tracks and paths and the proposed wind farm infrastructure.

Following identification of receptors at risk, these are ranked according to their size and sensitivity. **Table 6.2F** presents the coefficients placed on particular receptor types.

**Table 6.2F: Coefficients for Receptor Ranking**

Nature of Feature	Feature Coefficient
Non-critical infrastructure (minor/private roads, tracks)	1
Watercourses and critical infrastructure (pipelines, motorways, dwellings and business properties etc.)	3
Sub-Community (settlement 1-10 residents)	6
Community (settlement of >10 residents)	8

### 5.5.2 Receptor Proximity

The proximity of an impact receptor is also critical in assessing the likely level of disruption it may suffer following an instability event. Based on this, two further coefficients – distance from infrastructure feature and relative elevation differences between the infrastructure feature and impact receptor - are applied in deriving an impact ranking. **Table 6.2G** and **Table 6.2H** present the coefficients derived for distance and elevation of impact receptors.

**Table 6.2G: Coefficient for Receptor Proximity**

Distance from Coefficient Feature	Distance Coefficient
> 1 km	1
100 m – <1 km	2

Distance from Coefficient Feature	Distance Coefficient
10 – <100 m	3
0 – <10 m	4

**Table 6.2H: Coefficient for Impact Feature Elevation**

Relative Elevation of Feature	Elevation Coefficient
0 -<10 m	1
10 – <50 m	2
50 – <100 m	3
> 100 m	4

Based on distance to impact receptors, in this instance we have identified watercourses to be the most sensitive receptor near the Proposed Development. The other receptors have been discounted, either they are not present or distance to receptor mitigates risk. Watercourses are the principal receptor as they are at risk of not only direct impact from a peat slide but potentially the watercourse creates a pathway to impact other receptors indirectly, either ecological or potential water users downstream. Based on **Table 6.2F** the watercourses and site infrastructure would have an impact receptor coefficient (score) of 3 and then considering the distance to the receptor and the relative elevation differences on-site of receptors, a potential impact can be derived.

## 5.6 Hazard Ranking

In order to achieve a meaningful and manageable result from the hazard ranking, the results of the Risk Rating and Impact Rating have been normalised to a standard numerical scale (below).

**Table 6.2I: Rating Normalisation**

Risk Rating		Impact Rating	
Current Scale	Normalised Scale	Current Scale	Normalised Scale
Negligible <5	1	Very Low <10	1
Low 5 - <15	2	Low 11 - 20	2
Medium 15 - 30	3	High 21 - 30	3
High 31 - 50	4	Very High 31-50	4
Very High >51	5	Extremely High >51	5

The method of assessing probability of landslide, adverse consequence and hazard developed by SLR Consulting incorporates additional critical elements such as the substrate interface and coefficients for the receptor position, distance and elevation and as such is considered to be more rigorous than the assessment scheme proposed by the Scottish Government<sup>1</sup>. The Hazard Ranking scale does equate to the Scottish Government<sup>1</sup> scale, with rankings divided over four zones.

A simple multiplication of these coefficients would result in potentially large and unwieldy risk and impact rating numbers. SLR has therefore opted to normalise these values to bring them in line with the values used in the Scottish Government Guidance<sup>1</sup>, as illustrated in **Table 6.2J**.

**Table 6.2J: Hazard Ranking**

Hazard Ranking	Hazard Ranking Zone	Action
1-4	Insignificant	No mitigation action required although slide management and monitoring shall be employed. Slide management shall include the development of a site specific construction plan for peat areas.
5 - 10	Significant	As for Insignificant condition plus further investigation to refine the assessment combined with detailed quantitative risk assessment to determine appropriate mitigation through relocation or re-design.
11 - 16	Substantial	Consideration of avoiding project development in these areas should be made unless hazard mitigation can be put in place without significant environmental effect.
17-25	Serious	Unacceptable level of hazard; development within the area should be avoided.

The stability risk assessment has demonstrated that the majority of the Proposed Development lies within an area of negligible to low risk (90% of probe locations) with regards to stability based on **Figure 6.2.9**.

10% of probe locations identified a medium or high risk of peat instability across the Proposed Development. Following review, the majority of these locations are not considered to have either a potential impact on the development infrastructure, due to locality, either well away from influencing infrastructure, in a down gradient position or have no impact on the local watercourses (receptors). Therefore 15 medium risk sites have been identified and are discussed in the following section.

The stability risk assessment results presented in **Table 6.2K** shows the calculated hazard ranking associated with every location where there is a stability risk of medium or above, at or close to infrastructure. The particular mitigation measures to reduce the risk of instability occurring are dependent upon location and the type of proposed structure. Proposed mitigation measures and actions already undertaken to reduce the risk of peat instability occurring are also identified in **Table 6.2K**, together with the associated, revised hazard ranking. A more detailed discussion of the possible mitigation measures is presented in Section 6.0.

## 6.0 Slide Risk and Mitigation

### 6.1 Overview

A number of mitigation measure can be implemented to further reduce the risk levels identified across the Proposed Development site. These range from infrastructure specific measures to general good practice that should be applied across the Proposed Development to increase awareness of peat instability and enable early identification of potential displacement and opportunities for mitigation.

Risks may be mitigated by:

- undertaking site specific stability analysis using better quality geotechnical data, final design loads for infrastructure and detailed ground models in areas of specific concern; and
- precautionary construction measures – including use of monitoring, good practice and a geotechnical risk register relevant to all locations.

Mitigation measures are provided below specific to each area of “medium” risk. These mitigation measures will also help further reduce “low” and “negligible” risks to potential receptors. Sections 6.3 to 6.4 provide information on good practice pre-construction, during construction and post-construction (i.e. during operation).

### 6.2 Proposed Mitigation

As noted on **Figure 6.2.9**, where the risk assessment has identified a negligible or low risk of peat instability, no specific mitigation measures are necessary. However, in order to ensure best practise is employed, there would be a need for careful monitoring and the construction management must include careful design of both the permanent and temporary works appropriate for peat soils; these are discussed further in Section 6.3 to 6.4.

The areas of the infrastructure that were rated as medium or high risk, or above, were subjected to a hazard assessment; a number of areas were discounted as they do not fall within influencing distance of any of the key proposed site infrastructure. The procedure adopted was to review the peat slide risk data and identify those areas with a medium risk or greater, that were in close proximity or influencing distance of any of the proposed infrastructure or watercourses. Those risk areas where there is no development would not affect the natural stability of the peat.

**Table 6.2K** lists the 15 locations that have been identified to have either a “medium” or “high” risk of peat instability on the Proposed Development infrastructure. A variety of mitigation measures are recommended to reduce the risk of peat instability. Analysis of each location has shown that all can be mitigated to a Hazard Ranking of “insignificant”.

**Table 6.2K: Risk Register**

Location	Key Receptor	Risk Rating	Impact Rating	Hazard Ranking	Mitigation	Revised Hazard Ranking
1	Unnamed watercourse	Medium	Low	Significant	Access track impacted by localised areas of thick peat. Excavation of peat prior to construction would reduce risk and mitigate the risk of peat landslide to the southwest. Micro-siting of track out of thick peat would reduce the risk further in this area.	Insignificant
2	Unnamed watercourse	Medium	Low	Significant	T3 turbine impacted by localised areas of thin peat. Peat will be excavated prior to construction of turbine which will negate risk and mitigate against risk of peat landslide to the west.	Insignificant
3	Unnamed watercourse	Medium	Very Low	Insignificant	Access track impacted by localised areas of thin peat. Excavation of peat prior to construction would reduce risk and mitigate risk of peat landslide to the southeast. Micro-siting of track out of thick peat would reduce the risk further in this area.	Insignificant
4	Unnamed watercourse	Medium	Very Low	Insignificant	Turning head impacted by localised areas of thin peat. Excavation of peat prior to construction would reduce risk and mitigate the risk of peat landslide to the southeast. Micrositing of track out of thick peat would reduce the risk further in this area.	Insignificant
5	Wind farm infrastructure	Medium	Low	Significant	T5 temporary hardstanding impacted by localised areas of thick peat. Excavation of peat prior to construction would reduce risk and mitigate the risk of peat landslide to the northwest.	Insignificant
6	Wind farm infrastructure	Medium	Very Low	Insignificant	Access track impacted by localised areas of thin peat. Excavation of peat prior to construction would reduce risk and mitigate the risk of peat landslide to the northwest.	Insignificant
7	Wind farm infrastructure	Medium	Low	Significant	T6 temporary hardstanding and access track impacted by localised areas of thick peat. Excavation of peat prior to construction would reduce risk and mitigate the risk of peat landslide to the northwest. Micro-siting out of thick peat would reduce the risk further in this area.	Insignificant
8	Unnamed watercourse	High	Low	Significant	Access track impacted by localised areas of thick peat. Excavation of peat prior to construction would reduce risk and mitigate peat landslide to the northwest.	Insignificant

Location	Key Receptor	Risk Rating	Impact Rating	Hazard Ranking	Mitigation	Revised Hazard Ranking
					Micrositing out of thick peat or benching of slope would reduce the risk further in this area.	
9	Unnamed watercourse	Medium	Low	Significant	Proposed borrow pit impacted by localised areas of thick peat. Peat will be excavated as part of borrow pit excavations and restoration which will negate risk and mitigate against peat landslide to the northwest.	Insignificant
10	Wind farm infrastructure	Medium	Low	Significant	Access track impacted by localised areas of thin peat. Excavation of peat prior to construction would reduce risk and mitigate peat landslide to the northwest.	Insignificant
11	Wind farm infrastructure	Medium	Very Low	Insignificant	Access track impacted by localised areas of thick peat. Excavation of peat prior to construction would reduce risk and mitigate peat landslide to the northwest. Micrositing out of thick peat would reduce the risk further in this area.	Insignificant
12	Unnamed watercourse	Medium	Low	Significant	T7 temporary hardstanding and access track impacted by localised areas of thin peat. Excavation of peat prior to construction would reduce risk and mitigate peat landslide to the northwest. Micrositing out of thin peat would reduce the risk further in this area.	Insignificant
13	Unnamed watercourse	Medium	Low	Significant	T7 permanent hardstanding and access track impacted by localised areas of thick peat. Excavation of peat prior to construction would reduce risk and mitigate peat landslide to the northwest. Micrositing out of thick peat would reduce the risk further in this area.	Insignificant
14	Unnamed watercourse	High	Very Low	Insignificant	Access track impacted by localised areas of thin peat. Excavation of peat prior to construction would reduce risk and mitigate peat landslide to the west.	Insignificant
15	Unnamed watercourse	Medium	Low	Significant	Proposed borrow pit impacted by localised areas of thin peat. Peat will be excavated as part of borrow pit excavations and restoration which will negate risk and mitigate against peat landslide to the west.	Insignificant

### 6.3 Good Practice During Construction

The paragraphs below detail good practice that is recommended during construction. These measures are considered 'embedded mitigation' for the purposes of the assessment, and have been assumed to be in place for the purposes of the assessment presented in the EIA Report:

For excavated groundworks:

- Use of appropriate supporting structures around peat excavations to prevent collapse and the development of tension cracks.
- Avoid cutting trenches or aligning excavations across slopes (which may act as incipient head scarps for peat failures) unless appropriate mitigation has been put in place.
- Implement methods of working that minimise the cutting of the toes of slopes, e.g. working up-to downslope during excavation works.
- Monitor the ground upslope of excavation works for creep, heave, displacement, tension cracks, subsidence or changes in surface water content.
- Monitor cut faces for changes in water discharge, particularly at the peat-substrate contact.
- Minimise the effects of construction on natural drainage by ensures natural drainage pathways are maintained or diverted such that there is no significant alteration of the hydrological regime of the Proposed Development; drainage plans should avoid creating drainage/infiltration areas or settlement ponds towards the tops of slopes (where they may act to both load the slope and elevate pore pressures).

In addition to the above the following applies for cut tracks:

- Maintain drainage pathways through tracks to avoid ponding of water upslope.
- Monitor the top line of excavated peat deposits for deformation post-excavation.
- Monitor the effectiveness of cross-track drainage to ensure it water remains free-flowing and that no blockages have occurred.

For floating tracks:

- Prior to the construction, setting out the centre-line of the proposed track should include a walk over performed by the site manager or general foreman, along with the suitably qualified Geotechnical Engineer, and appropriate Clerk of Works. This should be carried out to check that the ground conditions/drainage paths are as expected, and "fine-tuning/micrositing" of the alignment if required.
- Weather policy should be agreed and implemented during works, e.g. identifying 'stop' rules (i.e. weather dependent criteria) for cessation of track construction or trafficking (e.g. allowing tracks to thaw following periods of hard frost).
- Allow peat to undergo primary consolidation by adopting rates of road construction appropriate to weather conditions.

For storage of peat:

- Ensure stored peat is not located in areas identified with 'Medium' or higher peat landslide likelihoods.
- Undertake site specific stability analysis for all areas of peat storage to ensure the likelihood of destabilisation of underlying peat is minimised. Analysis should consider

the slope angle of the storage location, the thickness of peat being stored and being loaded and use representative parameters for both the stored and underlying peat.

- Avoid storage of peat in areas of peat >1.5m in depth.
- Minimise haul distances for peat, storing as near to excavation as possible.
- Monitor effects of wetting / re-wetting stored peat on surrounding peat areas, and prevent water build up on the upslope side of peat mounds. Mitigate any run-off.

In addition to these control measures, the following good practice should be followed:

- A geotechnical risk register (GRR) should be prepared for the Proposed Development following intrusive investigations post-consent and location specific stability analyses – the risk register should be considered a live document and updated with site experience as infrastructure is constructed.
- All construction activities and operational decisions that involve disturbance to peat deposits should be overseen by an appropriately qualified geotechnical engineer with experience of construction on peat sites.
- Awareness of peat instability and pre-failure indicators should be incorporated in site induction and training to enable all site personnel to recognise ground disturbances and features indicative of incipient instability.
- Monitoring checklists should be prepared with respect to peat instability addressing all construction activities proposed for site.

## 6.4 Good Practice During Operation

Following cessation of construction activities, the following activities will be built into any monitoring of groundworks undertaken for the development:

- Ponding on the upslope side of infrastructure sites and on the upslope side of access tracks.
- Subsidence and lateral displacement of tracks.
- Blockage or underperformance of the installed site drainage system.
- Slippage or creep of stored peat deposits.
- Development of tension cracks, compression features, bulging or quaking bog anywhere in a 50m corridor surrounding the Proposed Development of any construction activities or site works.

This monitoring should be undertaken on a quarterly basis in the first year after construction, biannually in the second year after construction and annually thereafter; in the event that unanticipated ground conditions arise during construction, the frequency of these intervals should be reviewed, revised and justified accordingly.

## 7.0 Conclusion

The report has highlighted the complicated inter-relationship between all the aspects that have an effect on the stability of peat. Consequently, the discussion has also addressed areas of construction and drainage in order to avoid a stability problem rather than attempt to put it right after the event. The Proposed Development has been assessed for potential hazards associated with peat instability; the assessment has been based on:

- a walk-over survey by an experienced geologist;
- a thorough inspection of the digital terrain map;
- review of historical and geological maps and publications and aerial photography; and
- a detailed geotechnical probing exercise at 3,032 locations in areas of identified peaty soil/peat to determine the thickness thereof.

The overall conclusion regarding peat stability is that there are areas of medium risk of peat instability across the Proposed Development site and most have these have been avoided during the design process. For the 15 medium risk areas, a hazard impact assessment was completed which concluded that, with the employment of appropriate mitigation measures, all of the areas can be considered as an insignificant risk.

Additional mitigation measures have been identified in areas where hazards are already considered insignificant to further reduce the risk of potential hazards occurring.

The entire site can be considered to have localised areas of thick peat which have been avoided through layout design.

This report should be considered as the first stage in the development of a fundamental understanding of the various inter-relationships that govern and control the peat lands at the Proposed Development.

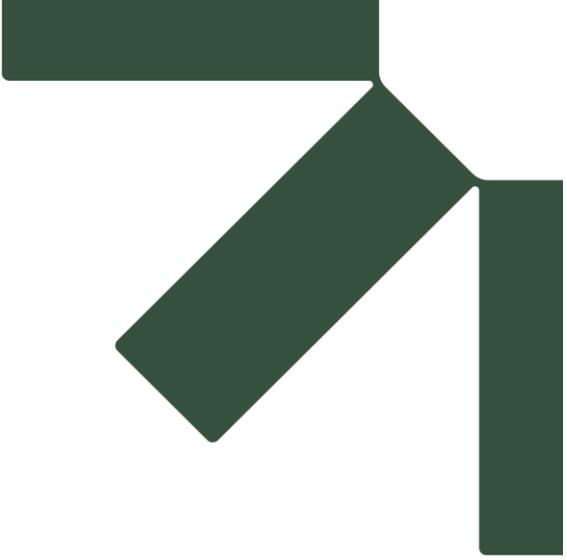

The commissioned assessment has purposefully kept the extent of physical intrusion into the sensitive peat areas to an absolute minimum. The results are considered appropriate for the planning application.

Good construction methods and appropriate micro-siting would also be effective at controlling residual peat landslide risk for lower risk locations at the Proposed Development. Providing that the recommended mitigation measures are put in place and adhered to, the risk of peat landslide as a result of the Proposed Development is not significant.

More detailed ground investigations will be required to facilitate the geotechnical design of the various foundations and access track. These will be incorporated into the CEMP which will be submitted to the Planning Authority for approval as part of the condition compliance prior to any site works commencing.

It is not the purpose of this report to provide a detailed scope for the investigation; however, it is believed that the strength and stiffness parameters are needed for turbine design and regular probes along access tracks to determine bearing capacity for either excavated or floated track design.

# Annex 6.2B: Peat Coring Data

## TA6.2: Peat Landslide Hazard and Risk Assessment

**Ben Sca Redesign Wind Farm**

**Ben Sca Wind Farm Limited**

SLR Project No.: 405.064982.00001

14 March 2024

# Peat Core Log

Hole No.  
**Auger 1**  
Sheet 1 of 1

Project: Balmeanach Wind Farm      Client: Wind 2 Project Limited      Date: 01/03/2023

Project No: 428.11223.00001      Logger: FS      Coordinates: E: 134125.00 N: 846859.00

Location: Balmeanach, Isle of Skye      Hole Type: HA      Method: Peat Core      Vertical Scale: 1:20

Water	Depth (m)	Sample Type	Depth	Recovery (%)	Depth (m) / Discontinuity Detail	Level (mAOD)	Legend	Stratum Description
	0.00 - 0.50	C	0.00 - 0.50	Recovery = 100%	0.50	0.50		Brown fibrous PEAT. Peat is very slightly amorphous with easily identifiable plant structure, very slight decomposition. (H3).
	0.50 - 1.00							Brown fibrous PEAT. Very slight amorphous material with easily identifiable plant structure, slight decomposition. (H3).
	1.00 - 1.50	C	0.50 - 1.00	Recovery = 100%	1.50	1.50		Brown fibrous PEAT. Very slight amorphous material with easily identifiable plant structure, moderate decomposition. (H3).
	1.50 - 2.00							Brown fibrous PEAT. Very slight amorphous material with easily identifiable plant structure, moderate decomposition. (H3).
	2.00 - 2.50	C	1.50 - 2.00	Recovery = 100%	2.45	2.50		Dark brown dry fibrous PEAT. Amorphous material present with recognizable but vague plant structure, moderately strong decomposition. (H5).
	2.00 - 2.50							Dark brown dry fibrous PEAT. Amorphous material present with recognizable but vague plant structure, moderately strong decomposition. (H5).
		C	2.00 - 2.50	Recovery = 100%				Peat Core Complete at 2.50m

**Remarks:**  
 1. Peat auger refused on gravel. 2. Strength descriptions based on field descriptions. 3. The von Post Classification for Peat Humification designates peat from H1 (No decomposition) to H10 (decomposed) based on the degree of humification.
